HIMMAT

DIGITAL LIFE SIMULATOR

Learn it. Break it. Recover from it. Master it.

A next-generation digital independence platform for parents, grandparents, and people who did not grow up with technology.

PROJECT CONCEPT & PRODUCT BLUEPRINT

Core idea: let people safely practise real digital situations, make mistakes without real-world risk, understand consequences, and learn to recover independently.

Prepared as a concept blueprint for the Build4Better challenge.

1. The opportunity

Build4Better asks teams to make technology easier and less intimidating for people who did not grow up with it. The goal is not simply to automate tasks for them; it is to help them understand, practise, and confidently complete everyday digital tasks.

Product insight: The strongest opportunity is to teach more than which button to press. Help users understand what happens when they press it, recognize risky situations, recover from mistakes, and become more independent.

HIMMAT is designed around safe practice and measurable skill development rather than a conventional chatbot or passive tutorial.

2. Product concept

HIMMAT: Digital Life Simulator is an interactive digital-world simulator. People experience realistic but fictional digital situations, choose what to do, see how their decisions change the outcome, and practise safer actions.

Example: a suspicious bank message

A learner receives a simulated message: “Your bank account will be blocked in 10 minutes. Verify your account immediately.”

• Inspect the sender and message details.

• Open or avoid a simulated link.

• Examine a fictional verification page.

• Decide what information is safe to share.

• See the simulated consequence of the decision.

• Replay the situation and practise a safer response.

The learner uses a safe simulation. No real bank account, money, password, OTP, or personal information is involved.

3. Core features

Reality Mode — realistic digital practice

Recreate familiar interactions such as messaging, mobile-wallet transactions, online shopping, video calls, phone settings, and government-style forms. The interfaces are fictional training environments.

Consequence Engine — decisions change the story

Each action leads to a defined branch. The learner sees what happened, why it happened, what a safer action would be, and what they can do differently.

Recovery Lab — practise what to do after a mistake

Teach recovery responses for situations such as sharing a simulated OTP, opening a suspicious link, making a simulated wrong transfer, changing a phone setting, or losing account access.

Digital DNA — personal skill intelligence

Build a profile of skill mastery across messaging, scam detection, online payments, privacy settings, and video calls. Recommend practice based on demonstrated weak areas.

Invisible AI Mentor — guidance without taking control

Explain unfamiliar buttons, answer questions in Urdu, Roman Urdu, or English, offer progressive hints, explain mistakes simply, and ask learners to explain their choices. The AI guides; the learner performs the task.

Family Intelligence Dashboard

With the learner's consent, family members can see skill progress, areas where support may help, and improvement over time. Do not expose private conversations or shame learners.

Digital Escape Room

Present a fictional digital crisis involving suspicious messages, account access, or impersonation. Learners complete a sequence of tasks to resolve it safely.

Memory Reinforcement Engine

Revisit skills that learners struggled with through new scenarios after a suitable interval. Measure retained ability, not just lesson completion.

4. Signature differentiator: Mistake Replay + What-if Engine

After a learner makes a risky choice in a scenario, HIMMAT records the decision path and lets them replay it. Rather than simply marking the answer wrong, it explains the sequence and offers a chance to change an earlier decision.

1. The learner receives an urgent simulated message.

2. They trust the sender without checking.

3. They open the simulated link.

4. They enter a fictional training OTP.

5. The simulated account is shown as compromised.

What-if replay

• What if I checked the sender first?

• What if I did not open the link?

• What if I contacted the bank through its official channel?

The learner rewinds to an earlier decision, chooses another action, and compares the outcomes. This turns a mistake into an interactive learning experience.

Engineering principle: use a deterministic scenario engine for branches and security outcomes. AI can provide hints and simplify explanations, but it should not invent the consequences.

5. End-to-end user journey

1. Create a learner profile: choose language, experience level, and accessibility preferences.

2. Initial skill assessment: identify existing knowledge and areas where the learner needs practice.

3. Enter a realistic simulation: choose a scenario such as banking, messaging, shopping, or video calls.

4. Make decisions: actions determine which branch of the scenario opens.

5. Review and recover: use Mistake Replay and Recovery Lab to understand and correct errors.

6. Complete a mastery test: try a new situation independently, with fewer or no hints.

7. Update Digital DNA: record skill progress and recommend the next challenge.

8. Share progress: show consent-based learning information on the family dashboard.

6. Initial scenario library

Scenario	Practice objectives
1. The Fake Bank Message	Identify suspicious senders; detect urgency and manipulation; understand OTP safety; practise safe reporting.
2. Send Money Safely	Select a recipient; verify account details; understand confirmation screens; respond to a simulated wrong transfer.
3. Video Call Rescue	Handle microphone permissions; fix camera issues; join a meeting; understand mute and speaker settings.
4. Online Shopping Trap	Identify suspicious stores; compare payment options; recognize fake discounts; check simulated order status.
5. Government Portal Challenge	Complete a fictional application; upload a sample document; understand required fields; correct a form mistake.

Build three scenarios to a high level of polish first, then expand the library. Use fictional interfaces inspired by familiar experiences; do not copy official login pages or collect real credentials, OTPs, identity documents, or payment details.

7. Technology stack

Layer	Suggested technology
Frontend	Next.js + TypeScript
UI components and styling	Tailwind CSS + shadcn/ui
Animation	Framer Motion
Backend	FastAPI (Python)
Database	PostgreSQL / Supabase
AI explanations	Gemini or OpenAI API
Scenario engine	Python + JSON-defined state machines
Analytics and charts	Recharts
Authentication	Supabase Auth
Deployment	Vercel + Render

8. High-level system architecture

Component	Responsibility
Next.js frontend	Learner experience, simulation screens, accessibility, and family dashboard.
FastAPI backend	Application APIs, session management, and coordination between services.
Scenario engine	Loads scenario definitions, validates actions, and controls branching.
Consequence and recovery engine	Produces deterministic outcomes, replay history, and recovery steps.
AI explanation engine	Provides plain-language explanations, hints, and multilingual support.
Skill assessment engine	Evaluates performance and updates skill mastery.
PostgreSQL	Stores profiles, scenarios, attempts, progress, and consent settings.

Important: the AI should not control the simulation's source-of-truth logic. The scenario engine should define the available actions, branches, consequences, recovery instructions, evaluated skill, and completion criteria.

9. What to show judges

Tell one coherent story rather than demonstrating a collection of disconnected features. The suggested demo is a two-minute journey showing a fictional learner becoming more independent.

Time	Demo segment
0:00–0:20	Introduce a fictional mother who depends on her son when an unfamiliar digital message arrives.
0:20–0:45	Show Reality Mode with a realistic simulated bank message and let her choose an action.
0:45–1:10	Show the Consequence Engine changing the simulation based on her decision.
1:10–1:30	Use Mistake Replay to rewind, explain the mistake, and choose a safer action.
1:30–1:45	Present a new scenario without hints to demonstrate independent mastery.
1:45–2:00	Show the family dashboard and the learner’s skill progress.

Suggested closing line:

“We don't want parents to call their children every time technology becomes confusing. We want them to become confident enough to handle it themselves. HIMMAT doesn't do things for them. It prepares them for the real world.”

10. Development priorities

Priority	Features
P0 — Essential	Realistic simulator, branching scenarios, consequence engine.
P1 — Differentiators	Mistake Replay, Recovery Lab, Digital DNA.
P2 — Advanced	AI mentor, family dashboard, Urdu and Roman Urdu support.
P3 — Future vision	Voice-call simulations, deepfake awareness, adaptive scenario generation, spaced repetition.

Recommended MVP: five scenarios planned, three polished and fully interactive; Mistake Replay; adaptive skill scoring; and a functioning family dashboard.

11. Alternative product directions

Digital Time Machine

A platform where users travel through the consequences of digital decisions, rewind actions, and compare alternative outcomes. Core differentiator: decision history and consequence visualization.

ScamVerse

An interactive world containing simulated scammers, fake stores, suspicious calls, deepfake scenarios, and social-engineering challenges. Core differentiator: a complete digital threat-awareness environment.

Digital Independence OS

A personal operating environment that maps someone's digital abilities, identifies areas of dependency, and creates a journey toward independence. Core differentiator: measuring digital independence rather than course completion.

12. Why HIMMAT is the recommended direction

• Directly addresses the Build4Better problem statement.

• Goes beyond a conventional chatbot or voice assistant.

• Has meaningful engineering depth through scenario state, branching, replay, assessment, and analytics.

• Creates a clear, visual live demonstration.

• Measures demonstrated skill development and retention.

• Has a clear social-impact purpose and room to grow into a real product.

13. Competition submission reminders

• The participant rulebook specifies the official build window as 9:00 AM–5:00 PM PKT on 31 October 2026.

• Create a new GitHub repository at the start of the build window and commit progress regularly.

• Submit the final entry through Hackathon Hub by the deadline.

• Provide a working GitHub repository and a complete README.

• Provide a demo video no longer than two minutes.

• Clearly distinguish working features from simulations or mocked features.

• Document AI tools, third-party dependencies, known limitations, and the final submitted commit identifier.

• Stop development at the deadline and do not modify the submitted version unless organisers explicitly instruct otherwise.

These reminders are based on the Build4Better Participant Rulebook supplied for this project. Check official event announcements for any updates.

Final recommendation

Build HIMMAT as a Digital Life Simulator, not as a bundle of unrelated AI features. Make the simulation engine, consequence logic, and Mistake Replay the heart of the product. Use AI as a supportive explanation layer, and use the family dashboard to show progress without taking away the learner’s privacy or independence.

The central promise is simple:

Learn it. Break it. Recover from it. Master it.
